PHASE 4: Development Part 2

Dataset: https://www.kaggle.com/datasets/akram24/mall-customers

This dataset is used in retail and marketing analytics to understand customer behavior and preferences. It includes the following types of information:

- Customer ID
- Gender
- Age
- Annual Income
- Spending Score

A "customer ID" (Customer Identification) is a unique identifier assigned to each customer in a database or system. It is used to distinguish one customer from another and track their activities, purchases, interactions, and other relevant information.

Gender is one of the key factors in segmenting customers into distinct groups. For example, stores may tailor their product offerings and marketing strategies differently for male and female customers.

Age is a fundamental factor for segmenting customers into groups. Different age groups may have distinct preferences, shopping behaviors, and income levels. For example, retailers often distinguish between teenagers, young adults, middle-aged individuals, and seniors.

The annual income of mall customers is a crucial demographic variable that helps businesses and mall operators understand the spending capacity and shopping preferences of their customer base.

Spending score is a metric used to assess and quantify a customer's purchasing behavior within a mall.

Performing K-Means Clustering on given data

K-Means Clustering:

K-Means Clustering is an Unsupervised Learning algorithm, which groups the unlabeled dataset into different clusters. Here K defines the number of predefined clusters that need to be created in the process, as if K=2, there will be two clusters, and for K=3, there will be three clusters, and so on.

Cost Function: Inertia is a metric used to evaluate the quality of a clustering algorithm, particularly the K-means algorithm. It measures the sum of squared distances between each data point and its assigned centroid. In other words, it measures how far the data points are from their assigned cluster centers.

The K-means algorithm tries to minimize the inertia by iteratively updating the cluster centers until the inertia cannot be reduced any further. A lower inertia value indicates that the clusters are more compact and well-separated, while a higher inertia value indicates that the clusters are more spread out and overlapping.

How does the K-Means Algorithm Work?

The working of the K-Means algorithm is explained in the below steps:

Step-1: Select the number K to decide the number of clusters.

Step-2: Select random K points or centroids. (It can be different from the input dataset).

Step-3: Assign each data point to their closest centroid, which will form the predefined K clusters.

Step-4: Calculate the variance and place a new centroid of each cluster.

Step-5: Repeat the third steps, which means re-assign each datapoint to the new closest centroid of each cluster.

Step-6: If any reassignment occurs, then go to step-4 else go to FINISH.

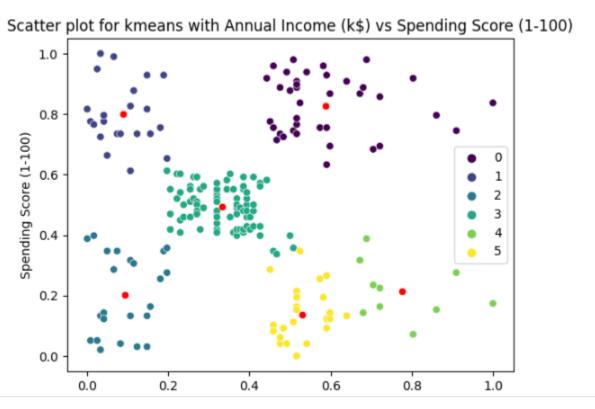

Step-7: The model is ready.

              sns.scatterplot(x=centers[:,0], y=centers[:,1], color = 'red')
              plt.show()
              return dataset, labels
[ ]: pkm = PerformKMeans(X)
     feature_set1 = X.columns.drop(["Age","Gender"])
     feature_set1 = X.columns.drop(["Gender", "Spending Score (1-100)"])
feature_set3 = X.columns.drop(["Gender", "Annual Income (k$)"])
feature_set4 = X.columns.drop(["Gender"])
 # fit
 dataset = X.loc[:,feature_set4]
 labels = km.fit_predict(dataset)
 centers = km.cluster_centers_
 inertia = km.inertia_
 # print results
print("inertia: ", inertia)
 print("centers: \n", centers)
```

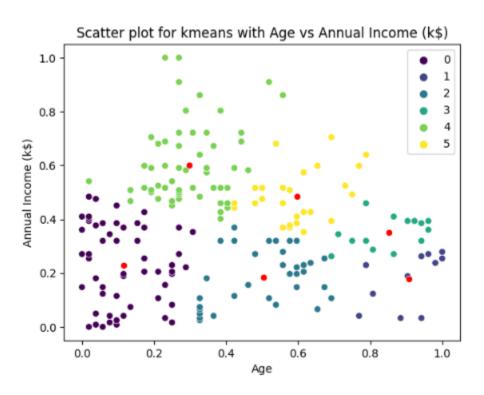

pkm.plot_clusters(feature_set1, k=6)

Process:

- 1. We load the dataset, select the relevant columns, and encode the "Genre" column using Label Encoding to convert it to numerical values.
- 2. We standardize the features using StandardScaler to make them comparable in terms of scale.
- 3. We specify the number of clusters (k) as 5 in this example, but you can adjust it based on your dataset and problem.
- 4. We perform K-Means clustering and obtain cluster labels for each data point.
- 5. We add the cluster labels to the original DataFrame to associate each data point with its cluster.
- 6. We visualize the clusters by creating a scatter plot of "Annual Income" and "Spending Score," where data points are colored by their cluster labels, and the cluster centroids are marked in red.
